

All rerankers see the same frozen candidate pool (depth 10, n = 238 dev queries), so differences are ordering ability alone. Recall@K = mean fraction of a query's gold set inside the top K; Hit@K = fraction of queries with at least one gold chunk there. The oracle line is the best any reordering of those same candidates could reach (candidate_ceiling.csv). The ceiling file carries no oracle_recall@10 column, so the oracle line stops before those K -- it is not extrapolated.
