

Where reranking helps and where it hurts (hit@1 vs 'original_ranking@10')

Cell = mean hit@1 of that reranker minus the baseline's mean on the same subgroup's queries; rows are ordered by the overall effect, best first. The colour scale is diverging and centred exactly at 0 with symmetric limits (± 0.500), so red cells are real regressions and not a lighter shade of blue -- but one badly-behaved reranker sets that range, which is why the well-behaved rows look pale; read their printed values. Subgroups overlap (a query carries several tags) and small-n subgroups are noisy -- n is in the tick label. '-' = the reranker scored no query in that subgroup.
